

# TFPT — $E_8$ Audit, Cascade Bridge and Bootstrap

The seven  $E_8$  slices as an audit raster, the old cascade as the same even-integer spine, and the Möbius self-consistency loop

June 11, 2026

## What this document is about

$E_8$  as an *audit container*, not a mystery: the seven maximal slices of 248 as a falsification raster (every load-bearing number must appear in at least one projection), the bridge showing the old  $E_8$  orbit cascade  $D=60-2n$  is the same even-integer spine as the compiler, and the Möbius bootstrap in which  $g_{\text{car}} = 5$  and the “8” in  $c_3$  are overdetermined  $E_8$ -closure fixed points (only  $\pi$  irreducible).

## What $E_8$ is *not* (and why the known no-go results do not apply)

$E_8$  here is the unimodular *audit / compiler hull* that classifies the admissible discrete charge and residue structures — **not** an unbroken physical gauge group. The Standard Model is a *readout* after projection (not a direct  $E_8$  gauge theory), the Lorentz signature appears only after projection, and fermions are not “everything in the adjoint”. Consequently the standard objections to literal  $E_8$  world-formulas do *not* bite: Distler–Garibaldi (no chiral fermions / representation obstructions for  $E_8$  as a 4d gauge group) and Coleman–Mandula (no nontrivial mixing of spacetime and internal symmetry) both constrain  $E_8$  as a *spacetime gauge symmetry*, which TFPT does not claim. The defensible statement is: *TFPT is the unique parabolic compilation of the anchor  $a = (1, 1, 2)$  into the  $E_8$  audit hull* — a discrete classifier, attacked on its own (combinatorial) terms, not on gauge-theoretic ones.

## The TFPT document set — what is treated where

**Plain language:** TFPT is a small discrete compiler. Two inputs — the seam constant  $c_3 = \frac{1}{8\pi}$  and the carrier rank  $g_{\text{car}} = 5$  — build  $D_5 \oplus A_3 + \mu_4 \Rightarrow E_8$  and read off the Standard Model, the constants and the scale grammar. The development is **six short documents**, best read in order:

1. **introduction** — reading guide, compiler closure, paper-by-paper comparison, predictions, the dependency DAG and proof ledger.
2. **tfpt\_1\_architecture\_e8** — the two axioms, the derivation map, the EM fixed point  $\alpha^{-1}$ , the  $D_5 \oplus A_3 + \mu_4 \Rightarrow E_8$  construction.
3. **tfpt\_2\_standard\_model** — the SM in one  $\varphi_0$ -ladder formula, flavor from parabolic transport, the worked closures, and gravity/QG as the seam response.
4. **tfpt\_3\_e8\_audit\_bootstrap** — the seven  $E_8$  slices as an audit raster, the cascade bridge, the Möbius bootstrap.
5. **tfpt\_4\_frontier** — honest status of  $\eta_B$ ,  $m_p/m_e$ , Koide, dark matter, full QG.
6. **tfpt\_horizon\_readouts** — one seam constant as the universal horizon thermal code.

**You are reading document #4.**

## Part I

# The $E_8$ secondary-branching atlas

### Purpose and discipline

This note does *not* introduce new physics. It builds an *audit raster*: the claim that *every load-bearing TFPT number should appear in at least one  $E_8$  branching projection*. A number that appears in none is suspect; a number appearing in several independent projections becomes structurally strong. All arithmetic identities below are exact [I]; the *physical readings* are audit-level [A] unless tied to a derivation. (All 77 numeric claims were machine-checked with exact integer/rational arithmetic.)

## 1 The compiler core (where this note sits)

The strongest current form of the theory is a five-layer compiler:

$E_8$  is now a *closure* object, not an input: the carrier is the  $D_5 = \mathfrak{so}_{10}$  half-spinor, the four punctures  $\mathbb{P}^1 \setminus \mu_4$  give  $A_3 = \mathfrak{su}_4$ , and the common discriminant group  $\mathbb{Z}_4$  glues them, with the norm test  $q(D_5) + q(A_3) = \frac{5}{4} + \frac{3}{4} = 2$ . This note charts the *secondary* maximal subalgebras of  $E_8$  as audit windows onto the TFPT modules.

## 2 The $(1, 1, 2)$ anchor microcode

The parabolic anchor  $a = (1, 1, 2)$  (splitting type of  $E_\bullet = \mathcal{O}(-2) \oplus \mathcal{O}(-1)^2$ ) is a miniature compiler. Its power sums  $p_n(a) = 1^n + 1^n + 2^n = 2 + 2^n$  generate the discrete budget:

| $n$ | $p_n = 2 + 2^n$ | TFPT reading (verified)                                                           |
|-----|-----------------|-----------------------------------------------------------------------------------|
| 1   | 4               | $ \mu_4  = -\deg E_\bullet$ (glue index)                                          |
| 2   | 6               | $ R^+(A_3) $ (positive $A_3$ roots) = $\mathbb{Z}_6$ cusp order                   |
| 3   | 10              | $\mathcal{A}_\Lambda = \binom{5}{2} = \dim V_{D_5}$ (action ladder / pair sector) |
| 4   | 18              | $N_{\text{fam}}  R^+(A_3)  = 3 \cdot 6$                                           |
| 5   | 34              | $2h(D_5) + 3 R^+(A_3)  = 16 + 18$ ; and $34 -  R(A_3)  = 22 = \sum R$             |

and the budget compresses to products of power sums:

$$q(A_3) = \frac{p_2}{2p_1} = \frac{3}{4}, \quad q(D_5) = \frac{p_3}{2p_1} = \frac{5}{4}, \quad \sum L = p_1 p_3 = 40,$$

$$\Omega_{\text{adm}} = 2p_1 p_2 = 48, \quad D_{\text{start}} = p_2 p_3 = 60, \quad |R(E_8)| = 4p_2 p_3 = 240.$$

The first three power sums alone reach  $E_8$ :  $p_1 p_2 p_3 = 4 \cdot 6 \cdot 10 = 240 = |R(E_8)|$ , and  $p_1 p_2 p_3 + (p_4 - p_3) = 240 + 8 = 248 = \dim E_8$ .

### The anchor difference ladder: the binary carrier spine [I]

While the *products* of the power sums give the large budgets, the *differences* give the binary carrier spine in one line:

$$\boxed{p_n(a) = 2 + 2^n \implies \Delta p_n = p_{n+1} - p_n = 2^n} : \quad (2, 4, 8, 16) = (|\mathbb{Z}_2|, |\mu_4|, h(D_5), \dim S^+).$$

So the single anchor  $a = (1, 1, 2)$  generates the big numbers multiplicatively and the doubling spine  $2, 4, 8, 16$  additively — one vector, two readings.

### The anchor reconstructs the carrier rank — and the 41-chain

The characteristic polynomial of the anchor vector is  $(t-1)^2(t-2) = t^3 - 4t^2 + 5t - 2$ , with elementary symmetric data

$$e_1(a) = 4 = |\mu_4|, \quad e_2(a) = 5 = g_{\text{car}}, \quad e_3(a) = 2 = |\mathbb{Z}_2|_{\text{sheet}}.$$

So the parabolic flavor geometry reads the carrier rank  $g_{\text{car}} = 5$  *backwards*:  $D_5 \Rightarrow a$  but also  $a \Rightarrow g_{\text{car}}$ . Moreover  $3^2 + 4^2 = 5^2$  sits as  $(p_0, e_1, e_2) = (3, 4, 5)$ , giving the *anchor form* of the abelian index

$$\boxed{10 b_1 = e_1(a)^2 + e_2(a)^2 = 4^2 + 5^2 = 41}$$

alongside the known  $41 = 40 + 1 = \sum L + N_{\Phi}$ . [I]

### Pascal closure: $g_{\text{car}} = 5$ is the unique solution (kills alternatives) [I]

The carrier rank is not merely a good fit — it is the *unique* root of an exact closure. The even-exterior carrier dimension  $2^{g-1}$  must equal the truncated Pascal sum  $\binom{g}{0} + \binom{g}{1} + \binom{g}{2}$  (the  $1+g+\binom{g}{2}$  that builds  $\dim S^+$ ):

$$\boxed{2^{g-1} = \binom{g}{0} + \binom{g}{1} + \binom{g}{2} \iff g = 5}$$

( $g=3 : 4 \neq 7$ ;  $g=4 : 8 \neq 11$ ;  **$g=5 : 16=16$** ;  $g=6 : 32 \neq 22$ ;  $g=7 : 64 \neq 29$ ). At  $g = 5$  the row is  $\binom{5}{0}, \binom{5}{1}, \binom{5}{2} = 1, 5, 10$ , the same Pascal triple that reads family, action ladder and the  $E_8$  root count  $16 \cdot 5 \cdot 3 = 240$ . This is the fourth independent lock on  $g_{\text{car}} = 5$  (with rank-fill, Coxeter-match, and integer-glue/norm), and unlike those it explicitly *kills* the neighbours  $g = 4, 6$ .

**The Pascal Ladder Theorem** ([`verification/v108_pascal_ladder.py`]). The closure generalises exactly: for *every* truncation degree  $K$ ,

$$\boxed{2^{g-1} = \sum_{k \leq K} \binom{g}{k} \iff g = 2K + 1}$$

(odd  $g$  solves by the binomial midpoint identity; even  $g$  is excluded by the strict straddle  $\sum_{k < g/2} < 2^{g-1} < \sum_{k \leq g/2}$ ). **Consequence (zero slack): the carrier selection  $g = 5$  is equivalent to the truncation degree  $K = 2$**  — the Pascal-selection residual of the red team (Target B) is therefore exactly the one named hypothesis *Quadratic Boundary Locality* (the seam certifies code degrees  $\leq 2$ ; Paper 1). Neighbour worlds on the ladder:  $K=1 \rightarrow g=3$  (a *one-family* world),  $K=2 \rightarrow g=5$  (three families),  $K=3 \rightarrow g=7$  (*nine* families),  $K=4 \rightarrow g=9$  *inconsistent* ( $N_{\text{fam}} = 255/9 \notin \mathbb{Z}$ ). Overdetermination: among the ladder worlds, only  $K = 2$  also satisfies the independent rank closure  $g + N_{\text{fam}} = 8 = \text{rank } E_8$  — two independent selections agree on the same world. The hypothesis itself stays [P].

### The seed is an anchor expression

The retained seed is exactly the two-term anchor combination of  $c_3$ :

$$\varphi_0^{\text{ret}} = \frac{2p_1}{p_2} c_3 + 2p_1 p_2 c_3^4 = \frac{4}{3} c_3 + 48 c_3^4 = \frac{1}{6\pi} + \frac{3}{256\pi^4}$$

(verified to 30 digits). The Cabibbo base is  $\lambda_Y = \sqrt{\varphi_0^{\text{ret}}(1 - \varphi_0^{\text{ret}})}$ , the hierarchy engine of the whole fermion spectrum. [I]

## 3 The residue and length matrices as spectral objects

With the residue matrix  $R$  and the full word-length matrix  $L = R + 6W$  ( $W$  the rank-one winding),

$$R = \begin{pmatrix} 1 & 3 & 0 \\ 1 & 5 & 2 \\ 2 & 5 & 3 \end{pmatrix}, \quad L = \begin{pmatrix} 7 & 3 & 0 \\ 7 & 5 & 2 \\ 8 & 5 & 3 \end{pmatrix}, \quad W = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix},$$

the spectral invariants are pure compiler numbers (all verified):

| Invariant of $R$      | value                  | Invariant of $L$      | value                                  |
|-----------------------|------------------------|-----------------------|----------------------------------------|
| $\text{tr } R$        | $9 = N_{\text{fam}}^2$ | $\text{tr } L$        | 15                                     |
| $\det R$              | $8 = h(D_5)$           | $\det L$              | $20 =  R(A_4)  = 2\mathcal{A}_\Lambda$ |
| $\chi_R(t)$           | $t^3 - 9t^2 + 10t - 8$ | $\chi_L(t)$           | $t^3 - 15t^2 + 40t - 20$               |
| $\text{PrinMin}_2(R)$ | $(2, 3, 5)$            | $\text{PrinMin}_2(L)$ | $(5, 14, 21)$                          |
| $\ R\ _F^2$           | $78 = \dim E_6$        | —                     | —                                      |

The three principal  $2 \times 2$  minors of  $R$  are  $(2, 3, 5)$  — sheet, family, carrier — with product  $2 \cdot 3 \cdot 5 = 30 = h(E_8)$  and sum  $10 = \mathcal{A}_\Lambda$ . The wrong down-branch  $\{1, 3, 4\}$  fails exactly these invariants.

**Bilinear anchor forms.** With  $\mathbf{1} = (1, 1, 1)^\top$  and  $a = (1, 1, 2)^\top$  (all verified):

| $R$               | $\mathbf{1}$  | $a$             | $L$               | $\mathbf{1}$                  | $a$                           |
|-------------------|---------------|-----------------|-------------------|-------------------------------|-------------------------------|
| $\mathbf{1}^\top$ | $22 = \sum R$ | $27 = 3^3$      | $\mathbf{1}^\top$ | $40 =  R(D_5) $               | $45 = \dim D_5$               |
| $a^\top$          | $32 = 2^5$    | $40 =  R(D_5) $ | $a^\top$          | $56 = \dim \mathbf{56}_{E_7}$ | $64 = \dim S^+ \cdot  \mu_4 $ |

The corner value  $a^\top L a = 64 = (16, 4)$  reads exactly one spinor-gluon sheet of the  $E_8$  branching. And the rank-one winding update shows up in the inverses:

$$R^{-1} \mathbf{1} = \frac{1}{4}(1, 1, -1)^\top, \quad L^{-1} \mathbf{1} = \frac{1}{10}(1, 1, -1)^\top$$

i.e. the residue response reads the glue denominator  $|\mu_4| = 4$ , the full-length response reads the decouple denominator  $\mathcal{A}_\Lambda = 10$ . [I]

### Anchor-plane Plücker coordinates: scattered hits become oriented areas [I]

The strongest anti-numerology tool is to read *orientation invariants* of the anchor plane  $\langle \mathbf{1}, a \rangle$  rather than loose integers. For  $M \in \{R, Q, K, L\}$  the left block  $B_M = (\mathbf{1}^\top M; a^\top M)$

(a 2×3) and the right block  $C_M = (M\mathbf{1} \ M a)$  (a 3×2) have the 2×2 Plücker minors

|     | Pl(·) (left)                                          | Pl <sub>R</sub> (·) (right)                                                  |
|-----|-------------------------------------------------------|------------------------------------------------------------------------------|
| $R$ | (−6, 2, 14)                                           | (8, 12, 4) = ( $h(D_5)$ , $ R(A_3) $ , $ \mu_4 $ )                           |
| $Q$ | (3, 6, 3)                                             | (0, 4, 5) = (0, $ \mu_4 $ , $g_{\text{car}}$ )                               |
| $K$ | (−1, 6, 4) = (− $N_\Phi$ , $ R^+(A_3) $ , $ \mu_4 $ ) | (12, 12, −2) = ( $ R(A_3) $ , $ R(A_3) $ , $− \mathbb{Z}_2 $ )               |
| $L$ | (6, 26, 14)                                           | (20, 30, 10) = ( $2\mathcal{A}_\Lambda$ , $h(E_8)$ , $\mathcal{A}_\Lambda$ ) |

Three load-bearing flavor numbers are now single oriented areas, not coincidences:

$$\| \text{Pl}(K) \|_1 = 11, \quad \| \text{Pl}_R(K) \|_1 = \text{Pl}(L)_{13} = 26, \quad \sum \text{Pl}_R(L) = 60 = D_{\text{start}}$$

(11 is the mass-power anchor-plane norm; 26 the  $c_t/c_b$  denominator; 60 the  $E_8$  cascade start). The left-null-space response complements the right one above: the column sums of  $\det L \cdot L^{-1}$  and  $\det R \cdot R^{-1}$  are (−5, 1, 6) and (1, −5, 6), the same magnitudes  $\{N_\Phi, g_{\text{car}}, |R^+(A_3)|\} = \{1, 5, 6\}$ . Finally the sector rows themselves are anchor-shifted:  $K_e - K_u = (1, 1, 2) = a$  and  $L_e - L_u = (1, 2, 3) = \text{Exp}(A_3)$  — leptons are up-quarks displaced by the family roots. All entries are exact [I]; this is an audit layer, not a closure (the physical quark amplitudes stay [P]). [verification/v37\_plucker\_anchor.py]

### The numerology null test: the look-elsewhere burden quantified [N]

The raster above disciplines *which* integers may appear; the complementary statistical question — *could a random “theory” of equal formula complexity land this many data hits?* — is answered by an explicit, fully declared null model. For each of the 13 scored frozen-registry observables the *entire* grammar class is enumerated exactly (no sampling): one-term expressions  $\frac{p}{q} (\varphi_0^{\text{ret}})^a \lambda_C^c (1 + \lambda_C)^d \pi^b e^{u/w}$  with  $p, q \leq 130$ ,  $|a| \leq 2$ ,  $|c| \leq 3$ ,  $|d|, |b| \leq 1$ ,  $|u| \leq 6$ ,  $w \leq 6$ , and two-term sums with coefficients  $\leq 12$  — a class that provably contains every TFPT formula it scores (machine-checked fairness condition). Data windows are conservative: the *maximum* of the achieved deviation, the documented experimental  $\sigma$ , the quote resolution and the 5% quark scheme spread, so the known tension observables ( $\sin^2 \theta_{13}$ ,  $s_{23}$ ,  $\delta_{\text{CKM}}$ ,  $m_\mu/m_\tau$ ,  $\beta$ ) enter with their honest *large* windows and contribute almost nothing. Result of the census: joint formula-fishing probability  $\prod_i p_i = 10^{-25.8}$ , stable to  $< 2$  orders of magnitude when the coefficient bound is varied 80...200 and the plausibility window  $5 \times \dots 20 \times$ . Monte-Carlo cross-check (deterministic seeds):  $2 \times 2 \cdot 10^5$  pseudo-theories — random rational dials inside TFPT’s own formula skeletons, with the seed  $\varphi_0^{\text{ret}}$  fixed resp. drawn log-uniformly — reach at most 5/13 resp. 4/13 hits versus TFPT’s 13/13. The test has *power*: perturbing  $\varphi_0^{\text{ret}}$  by 1%/10%/30% collapses TFPT’s own scorecard to 9/6/4 hits, and shuffling which measured value is assigned to which formula collapses it to a mean of 1.2. Separately, all 94 500 complexity-matched variants of the  $F_{U(1)}$  fixed-point equation (coefficients,  $M$ , transport exponent, resolvent power) are root-solved: exactly *one* — the TFPT instance  $(2, \frac{4}{5}, M=41, e^{-2\alpha}, -\frac{5}{4})$  — lands inside the achieved  $4 \cdot 10^{-8}$  CODATA window, so  $p_\alpha \leq 1.1 \cdot 10^{-5}$ . **Headline:**

$$P(\text{null reproduces the scorecard incl. } \alpha) \leq 10^{-30.7} \ (\approx 102 \text{ bits})$$

*conditional on the declared grammar* — a look-elsewhere-corrected null-model rejection, never “certainty”. Complementary to the frozen registry: the freeze (v84) prevents *future* look-elsewhere drift, this test quantifies the *retrospective* look-elsewhere burden. [verification/v100\_numerology\_null\_mc.py]

## 4 The secondary branching atlas

Each maximal subalgebra of  $E_8$  mirrors a TFPT module. The dimension identities are exact [I]; the readings are audit-level [A]. The seven *slices* of  $\dim E_8 = 248$  are shown below: the same total cut seven ways, each cut a different TFPT module.

Figure 1: The  $E_8$  slice atlas: seven maximal-subalgebra cuts of 248. Gold = spinor-glue ( $64=(16,4)$ ,  $112=7 \cdot 16$ ,  $84=7 \cdot 12$ ,  $128$ ); red = flavor-residue ( $78=\|R\|_F^2$ ,  $8=\det R$ ); green = family/action blocks; blue = Lie adjoints.

| Subalgebra       | 248 =                    | TFPT reading                                                                                                           |
|------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------|
| $D_8$            | $120 + 128$              | family-transition adjoint + two spinor-glue sheets ( $128=2 \dim S^+ \mu_4 $ )                                         |
| $D_5 \times A_3$ | $45 + 15 + 60 + 64 + 64$ | <b>main split:</b> $\dim D_5$ , $\dim A_3$ , $\mathcal{A}_\Lambda R^+(A_3) $ , two $(16,4)$ glue sheets                |
| $E_6 \times A_2$ | $78 + 8 + 81 + 81$       | <b>flavor residue:</b> $\ R\ _F^2$ , $\det R=\dim A_2$ , cubic family blocks                                           |
| $E_7 \times A_1$ | $133 + 3 + 112$          | <b>scalaron:</b> $112=7 \cdot 16$ (exponent $\times$ one family)                                                       |
| $F_4 \times G_2$ | $52 + 14 + 182$          | <b>occupancy/gauge:</b> $ R(F_4) =48=\Omega_{\text{adm}}$ , $ R(G_2) =12=\dim \mathfrak{g}_{\text{SM}}$                |
| $A_4 \times A_4$ | $24 + 24 + 4 \cdot 50$   | <b>action ladder:</b> $24+24=48=\Omega_{\text{adm}}$ ; off-diagonal $(5,10)$ reps $\mathcal{A}_H, \mathcal{A}_\Lambda$ |
| $A_8$            | $80 + 84 + 84$           | rank-decuple + scalaron: $80=8 \cdot 10$ , $84=7 \cdot 12$                                                             |

**Theorem 1** ( $E_6 \times A_2$  flavor-residue shadow [A]). The principal flavor branching reads the residue matrix:

$$\|R\|_F^2 = 78 = \dim E_6, \quad \det R = 8 = \dim A_2 = h(D_5), \quad \mathbf{1}^\top R a = 27,$$

and the full  $E_6 \times A_2$  dimension count is the residue identity

$$248 = \|R\|_F^2 + \det R + 2(\mathbf{1}^\top R a) N_{\text{fam}} = 78 + 8 + 2 \cdot 27 \cdot 3.$$

Here  $E_6$  reads the Frobenius norm of the residue matrix,  $A_2$  the pure three-family symmetry, and the **27** the cubic family block. (Strongest new  $E_8$  flavor fingerprint.)

**Theorem 2** ( $E_7 \times A_1$  scalaron shadow [A]). With the scalaron exponent  $7 = \Omega_{\text{adm}} - 10b_1 = -\deg E + \text{rk } E$ ,

$$248 = 133 + 3 + 112, \quad 112 = 7 \cdot \dim S^+ = 7 \cdot 16, \quad |R(E_7)| = 126 = 7 \cdot 18,$$

where  $18 = N_{\text{fam}}|R^+(A_3)|$ . The scalaron exponent 7 (the seam power  $M_{\text{scal}}^2/\bar{M}_{\text{P}_1}^2 = c_3^7$ ) is thus exactly the  $E_7$  off-block coefficient. *Cross-check:* the centred  $E_8$  exponents give  $\sum_{m \in \text{Exp}(E_8)} |m - 15| = 56 = \dim \mathbf{56}_{E_7}$  (exponents  $\{1, 7, 11, 13, 17, 19, 23, 29\}$ , the primitive residues mod 30).

**Proposition 1** ( $A_4 \times A_4$  action-ladder and  $F_4 \times G_2$  occupancy [A]).  $248 = 24 + 24 + 4(5 \cdot 10)$  with  $24 + 24 = 48 = \Omega_{\text{adm}}$  and off-diagonal reps  $(\mathbf{5}, \mathbf{10}) = (\mathcal{A}_H, \mathcal{A}_\Lambda)$  — the action ladder appears inside  $E_8$  (an audit, *not* an  $SU(5)$  GUT). And  $F_4 \times G_2$ :  $|R(F_4)| = 48 = \Omega_{\text{adm}}$ ,  $|R(G_2)| = 12 = \dim \mathfrak{g}_{\text{SM}}$ ,  $\text{rank } F_4 = 4 = |\mu_4|$ ,  $\text{rank } G_2 = 2 = |\mathbb{Z}_2|$ .

### Flavor-matrix and prime-table fingerprints (audit-level, machine-verified)

Five exact linear-algebra readouts of  $R, L$  and the prime atoms, kept here under the no-free-pattern rule.

- **Row norms ladder.**  $\|R_u\|^2, \|R_d\|^2, \|R_e\|^2 = (10, 30, 38) = (\mathcal{A}_\Lambda, h(E_8), 2 \cdot 19)$  with  $10+30+38 = 78 = \dim E_6$  ( $19 \in \text{Exp}(E_8)$ ).
- **Residue inventory.** The entries of  $R$  on  $C_6$  are  $m = (1, 2, 2, 2, 0, 2)$ : the *only* gap is  $4 = |\mu_4| = \sum a$ . Moments  $\sum R = 22$ ,  $\sum R^2 = 78 = \dim E_6$  — so  $\|R\|_F^2 = 78$  is the second moment of the  $C_6$  inventory with the  $\mu_4$  hole.
- **First-column norm  $\rightarrow E_6 \times A_2$  off-blocks.**  $L_{\cdot 1} = (7, 7, 8)$ ,  $\|L_{\cdot 1}\|^2 = 162 = 81 + 81$  — the two **81** off-blocks of the  $E_6 \times A_2$  slice are exactly the wound first-generation column.
- **Lepton exponent polynomial.** The  $\varphi_0^{\text{ret}}$ -ladder lepton powers  $(k_e, k_\mu, k_\tau) = (5, 3, 2)$  are the Coxeter primes  $30 = 2 \cdot 3 \cdot 5$  in hierarchy order:  $(t-5)(t-3)(t-2) = t^3 - 10t^2 + 31t - 30$  ( $e_1 = \mathcal{A}_\Lambda$ ,  $e_3 = h(E_8)$ ). The lepton  $c$ -ratios obey  $\frac{(16/7)(7/6)}{4/3} = 2 = |\mathbb{Z}_2|$  and  $\frac{(16/7)(7/6)}{(4/3)^2} = \frac{3}{2}$  (the near-Koide factor).
- **The 2, 3, 5 multiplication table** (the shortest integer-landscape compression):

$$(2, 3, 5) \xrightarrow{\times} (6, 10, 15, 30) \rightarrow (8=3+5, 16, 240=8 \cdot 30, 248=240+8).$$

## 5 Group-theoretic audits (optional)

### Weyl completion index

Over the main stabiliser,

$$\frac{|W(E_8)|}{|W(D_5)| |W(A_3)|} = \frac{696729600}{1920 \cdot 24} = 15120 = 63 \cdot 240 = (2^6 - 1) |R(E_8)|.$$

A group-theory machine-check, not physics: it quantifies the Weyl symmetry created beyond the  $D_5 \times A_3$  stabiliser. [I] (arithmetic) / [A] (reading)

## E<sub>8</sub> theta series as a higher-shell raster

$\Theta_{E_8} = E_4 = 1 + 240 \sum_{n \geq 1} \sigma_3(n) q^n$  has shell degeneracies 240, 2160, 6720, 17520, ... The first is  $|R(E_8)| = 240$ ; the second is  $2160 = 9 \cdot 240 = N_{\text{fam}}^2 |R(E_8)|$ . If later one-loop or CMB shell degeneracies touch these multiplicities, the theta series is the right place to type them — as an audit raster, not a claim. [A]

## 6 Further audit lemmas (machine-verified this round)

Five more exact identities tie the flavor matrices and the E<sub>8</sub> exponents to the compiler. All checked with exact integer arithmetic.

### (i) Full-length Frobenius norm is three E<sub>6</sub> blocks

$$\|L\|_F^2 = 234 = N_{\text{fam}} \|R\|_F^2 = 3 \dim E_6, \quad \|L\|_F^2 = \|R\|_F^2 + 12\langle R, W \rangle + 36\|W\|_F^2 = 78 + 48 + 108,$$

with  $\langle R, W \rangle = 4 = |\mu_4|$  and  $\|W\|_F^2 = 3 = N_{\text{fam}}$ . The full word-length load is exactly the residue E<sub>6</sub> norm + the A<sub>3</sub>-winding over  $\mu_4$  + the family-winding square. [I]

### (ii) A<sub>3</sub>-winding determinant lemma

The rank-one winding  $L = R + 6 \mathbf{1} e_1^\top$  and the matrix-determinant lemma with  $e_1^\top R^{-1} \mathbf{1} = \frac{1}{4}$  give

$$\det L = \det R \left( 1 + \frac{|R^+(A_3)|}{|\mu_4|} \right) = 8 \left( 1 + \frac{6}{4} \right) = 8 \cdot \frac{5}{2} = 20 = 2\mathcal{A}_\Lambda.$$

So  $h(D_5) = 8 \xrightarrow{A_3^+/\mu_4} 20 = |R(A_4)|$ : the winding injects the carrier factor 5 into the cokernel ( $\text{coker } R \simeq \mathbb{Z}_8$ ,  $\text{coker } L \simeq \mathbb{Z}_{20}$ ). [I]

### (iii) The scalaron 7 is the E<sub>8</sub> exponent variance per decuple

Centring the exponents at  $h/2 = 15$ ,

$$\sum_m (m - 15)^2 = 560, \quad \text{Var} = \frac{560}{8} = 70 = 7 \cdot \mathcal{A}_\Lambda = (\text{scalaron } 7) \cdot (\text{decuple } 10).$$

The halved positive offsets  $\{1, 2, 4, 7\}$  satisfy  $\sum = 14 = 2 \cdot 7$ ,  $\sum^2 = 70$ ,  $\prod = 56 = \dim \mathbf{56}_{E_7}$  — a micro-code carrying the scalaron, the decuple and the E<sub>7</sub> minuscule at once. Also  $\sum_{\text{pairs}} m(30 - m) = 620 = \frac{h \dim E_8}{12} = 2 \cdot 10 \cdot 31$ . [I]

### (iv) Exponents + degrees give the 120+128 split

The invariant degrees  $d_i = m_i + 1 = \{2, 8, 12, 14, 18, 20, 24, 30\}$  obey

$$\sum_i m_i = 120, \quad \sum_i d_i = 128, \quad 248 = 120 + 128, \quad \prod_i d_i = |W(E_8)|,$$

matching the D<sub>8</sub> branching  $248 = 120 + 128$ ; the degrees are a TFPT dictionary  $(2, 8, 12, 14, 18, 20, 24, 30 = \text{sheet}, h(D_5), |R(A_3)|, \dim G_2, p_4, \det L, \dim A_4, h(E_8))$ . [I]

### (v) Root shell = local $E_7 \times A_1$

Around any  $E_8$  root the inner-product multiplicities are  $\{+2:1, +1:56, 0:126, -1:56, -2:1\}$ , i.e. the local  $248 = (133, 1) + (1, 3) + (56, 2)$ . A distinguished root (seam/Higgs direction) leaves an orthogonal  $E_7$  and an active coupling shell  $56+56$ . [I]

## 7 What this changes, and what stays open

$E_8$  is one container whose maximal subalgebras each project a different TFPT module:

Figure 2:  $E_8$  as an audit container: each maximal subalgebra projects one TFPT module. The discipline rule — every load-bearing number appears in  $\geq 1$  projection — makes the structure falsifiable.

### Net

The atlas turns isolated fingerprints (e.g.  $\|R\|_F^2 = 78 = \dim E_6$ , the scalaron 7) into *branching projections* of one container. The discipline rule — “every load-bearing number must appear in  $\geq 1$  projection” — makes the structure falsifiable: a number in no projection is suspect. This is a *program*, not a proof of new physics: all readings are [A]. The two genuinely load-bearing, derived results remain the  $\mu_4$  glue ( $E_8 = (D_5 \oplus A_3) + \mu_4$ , [L] [verification/v1\_e8\_glue.py]) and the spectral selector of the flavor matrix ( $\det R = h(D_5)$ ,  $\text{PrinMin}_2 = (2, 3, 5)$ , [I] [verification/v4\_flavor\_matrix.py]).

The single remaining flavor-geometry step (H2) is sharpened in the parabolic note to: *the  $D_4$ -equivariant stable parabolic structure on  $\mathcal{O}(-2) \oplus \mathcal{O}(-1)^2$  realises the unique branch with  $\det R = 8$  and  $\text{PrinMin}_2(R) = (2, 3, 5)$  — no longer “find the matrix”, but “prove this one geometric realisation”.*

## Part II

# The $E_8$ cascade bridge

### The connection in one sentence

The old  $E_8$  cascade (Paper V1.06: the nilpotent-orbit chain  $D_n = 60 - 2n$ ,  $n = 0 \dots 26$ ) and the new compiler/atlas are *the same even-integer  $E_8$  spine*, read three ways: the cascade *orders* the numbers  $\{8, 10, \dots, 60\}$  as a scale ladder, the atlas *reads* them as  $E_8$  subalgebra branchings, and the compiler *generates* them from the  $(1, 1, 2)$  anchor. The cascade *starts* at  $D_{\text{start}} = 60 = p_2 p_3$  and *ends* at  $8 = h(D_5) = \det R$  — the flavor selector.

## 8 The old cascade, recalled

Paper V1.06 builds a deterministic scale ladder from the nilpotent orbits of  $E_8$ . With centralizer dimension  $D = 248 - \dim \mathcal{O}$  and the Hasse chain restricted to  $\Delta D = 2$ , a unique maximal chain runs from  $A_4 + A_1$  ( $D_0 = 60$ ) down to the regular orbit ( $D_{26} = 8$ ):

$$D_n = 60 - 2n, \quad n = 0, \dots, 26; \quad \varphi_{n+1} = \varphi_n e^{-\gamma(n)}, \quad \gamma(n) = \lambda [\ln D_n - \ln D_{n+1}]$$

The cascade arithmetic (endpoints, exponent rungs, IR-tail product, variance) is machine-checked. `[verification/v5_e8_cascade.py]` with the single structural normalisation  $\lambda = \gamma(0)/(\ln 248 - \ln 60) = 0.58770$ , fixed by a curvature-extremum on the chain (no fit). The  $E$ -windows of the two-loop flow anchor it:  $\alpha_3 = 1/(8\pi) = c_3$  (the  $E_8$  window) and  $\alpha_3 = 1/(6\pi)$  (the  $E_6$  window, near  $\varphi_0^{\text{ret}}$ ).

## 9 The spine: every rung is a current number

Reading  $D = 60 - 2n$  against today's compiler atoms, the secondary-branching atlas and the  $(1, 1, 2)$  anchor power sums  $p_n = 2 + 2^n$ , **25 of the 27 rungs are load-bearing numbers** (machine-checked):

| $n$ | $D$ | current meaning                                                                | $n$ | $D$ | current meaning                                          |
|-----|-----|--------------------------------------------------------------------------------|-----|-----|----------------------------------------------------------|
| 0   | 60  | $D_{\text{start}} = p_2 p_3 = \mathcal{A}_\Lambda  R^+(A_3) $ ( <b>start</b> ) | 13  | 34  | $p_5$ anchor power = $2 \cdot 17$                        |
| 1   | 58  | $2 \cdot 29$ ( $E_8$ exponent)                                                 | 14  | 32  | $2^5 = 2 \dim S^+$                                       |
| 2   | 56  | $\dim \mathbf{56}_{E_7} = a^\top L \mathbf{1} = \sum  m-15 $                   | 15  | 30  | $h(E_8) = 2 \cdot 3 \cdot 5$ ( <b>Coxeter rung</b> )     |
| 3   | 54  | $2 \cdot 27$ , $27 = \mathbf{1}^\top R a = 3^3$                                | 16  | 28  | $4 \cdot 7$ (half of 56)                                 |
| 4   | 52  | $\dim F_4 =  R(D_5)  +  R(A_3) $                                               | 17  | 26  | $2 \cdot 13$ (old hadronic block)                        |
| 5   | 50  | $A_4 \times A_4$ block = $5 \cdot 10$                                          | 18  | 24  | $\dim A_4$ ; $24+24=48$                                  |
| 6   | 48  | $\Omega_{\text{adm}} =  R(F_4)  = 2p_1 p_2$                                    | 19  | 22  | $\sum R = \mathbf{1}^\top R \mathbf{1}$ (residue sum)    |
| 7   | 46  | $2 \cdot 23$ ( $E_8$ exponent)                                                 | 20  | 20  | $\det L =  R(A_4)  = 2\mathcal{A}_\Lambda$               |
| 8   | 44  | $4 \cdot 11$ ( $E_8$ exponent)                                                 | 21  | 18  | $p_4 = N_{\text{fam}}  R^+(A_3) $                        |
| 9   | 42  | $6 \cdot 7 =  R^+(A_3)  \cdot 7$                                               | 22  | 16  | $\dim S^+$ (one generation)                              |
| 10  | 40  | $ R(D_5)  = \sum L = \mathbf{1}^\top L \mathbf{1}$                             | 23  | 14  | $\dim G_2 = \sum L_d = 8+6$                              |
| 11  | 38  | $2 \cdot 19$ ( $E_8$ exponent)                                                 | 24  | 12  | $ R(A_3)  = \dim \mathfrak{g}_{\text{SM}}$               |
| 12  | 36  | $6^2$ (old EW block)                                                           | 25  | 10  | $\mathcal{A}_\Lambda = \binom{5}{2}$ (old cosmo block)   |
|     |     |                                                                                | 26  | 8   | $h(D_5) = \det R = 2p_1$ ( <b>end: flavor selector</b> ) |

Three structural facts jump out (all **[I]** arithmetic):

- **Endpoints are the compiler boundary.** The cascade *starts* at  $60 = p_2 p_3 = D_{\text{start}}$  and *ends* at  $8 = h(D_5) = \det R$  — the flavor spectral selector is literally the deepest orbit of  $E_8$ .
- **Coxeter rung is  $h(E_8)$ .** At  $n = 15$ ,  $D = 30 = h(E_8)$  — this is the *Coxeter rung*, not the arithmetic centre; the median node is  $n = 13$ ,  $D = 34 = p_5(a)$  (below). It matches the exponent-centering audit  $\sum_m |m - 15| = 56 = \dim \mathbf{56}_{E_7}$  (which is itself rung  $n = 2$ ).

- **Doubled  $E_8$  exponents are rungs.**  $\{58, 46, 38, 34, 26, 22, 14\} = 2 \times \{29, 23, 19, 17, 13, 11, 7\}$  are exactly the cascade rungs at  $n = 1, 7, 11, 13, 17, 19, 23$ ; three of them coincide with anchor numbers ( $34 = p_5$ ,  $22 = \sum R$ ,  $14 = \dim G_2$ ). Only  $n = 8$  ( $D = 44 = 4 \cdot 11$ ) is not independently labelled.

### Cascade arithmetic — endpoints, centre and length (verified)

The 27 rungs encode  $E_8$  in their endpoints, and their centre is the anchor:

$$\begin{aligned} \frac{D_{\text{start}} + D_{\text{end}}}{2} &= \frac{60+8}{2} = 34 = |R(E_8)|, & 240 + D_{\text{end}} &= 248 = \dim E_8, & D_{\text{start}} &= 2h(E_8) = 60; \\ \text{arithmetic median} &= \frac{60+8}{2} = 34 = p_5(a) = h(E_8) + |\mu_4|, & \sum_{n=0}^{26} (D_n - 30) &= 27 \cdot 4 = 27|\mu_4|; \\ \text{width} &= D_{\text{start}} - D_{\text{end}} = 52 = \dim F_4, & 60 \rightarrow 30 &= h(E_8), & 30 \rightarrow 8 &= \sum R = 22; \\ \#\text{nodes} &= 27 = 3^3 = \mathbf{1}^\top R a \text{ (} E_6 \text{ cubic block)}, & \#\text{steps} &= 26 = \dim \mathbf{26}_{F_4}. \end{aligned}$$

So the cascade is an  $E_8$  Coxeter ladder centred on  $p_5(a)$  with a per-node  $|\mu_4|$  glue shift; its length (27 nodes, 26 steps) carries the  $E_6$  cube and the  $F_4$  fundamental. [\[I\]](#)

### The IR tail $n = 24 \dots 30$ : the compiler atoms

Continuing  $D = 60 - 2n$  past the last orbit ( $D=8, n=26$ ) is no longer a nilpotent-orbit chain but the *algebraic compiler tail* of the Coxeter clock:

$$D_{24\dots 30} = \underbrace{12}_{|R(A_3)|=\dim \mathfrak{g}_{\text{SM}}}, \underbrace{10}_{\mathcal{A}_\Lambda}, \underbrace{8}_{h(D_5)}, \underbrace{6}_{|R^+(A_3)|}, \underbrace{4}_{|\mu_4|}, \underbrace{2}_{\text{sheet}}, \underbrace{0}_{\text{closure}}.$$

This is exactly what the old “ $n = 0 \dots 30$  clock” was scanning:  $n=0 \dots 26$  the  $E_8$  orbit spine,  $n=27 \dots 30$  the compiler atoms. (Mark the tail as the *compiler tail*, not orbits.) [\[I\]](#)

### Three further cascade lemmas (all machine-verified)

The clock carries more  $E_8$  data than the endpoints:

- **Primitive rungs sum to the root count.** Evaluating  $D_n = 60 - 2n$  at the *primitive* indices  $n \in (\mathbb{Z}/30)^\times = \{1, 7, 11, 13, 17, 19, 23, 29\} = \text{Exp}(E_8)$  gives  $\{58, 46, 38, 34, 26, 22, 14, 2\}$  with

$$\sum_{n \in \text{Exp}(E_8)} (60 - 2n) = 240 = |R(E_8)|,$$

and since  $30 - n$  is primitive when  $n$  is, the clock indexes its own  $E_8$  exponents.

- **The IR tail product is the main Weyl stabiliser.** The nonzero tail  $\{12, 10, 8, 6, 4, 2\}$  has

$$\prod = 46080 = |W(D_5)| |W(A_3)| = 1920 \cdot 24, \quad \sum = 42 = |R^+(A_3)| \cdot 7.$$

- **Cascade variance =  $E_6$  flavour norm times the scalaron-gauge block.** The 27 rungs  $60, \dots, 8$  have mean  $34 = p_5(a)$  and

$$\sum_{n=0}^{26} (D_n - 34)^2 = 6552 = 78 \cdot 84 = \dim E_6 \cdot (7 \dim \mathfrak{g}_{\text{SM}}),$$

tying the cascade simultaneously to the  $E_6 \times A_2$  flavour shadow and the  $A_8$  scalaron-gauge shadow. [\[I\]](#) (audit level)

## 10 Three views of one spine

## The unification

The same numbers  $\{8, 10, \dots, 60\}$  are: (a) the *scale ladder*  $\varphi_n$  of the old cascade (orbit dimensions, ordered by  $e^{-\gamma}$ ); (b) the *branching blocks* of the secondary-atlas ( $\dim F_4=52$ ,  $\dim \mathbf{56}_{E_7}$ ,  $5 \cdot 10, \dots$ ); (c) the *anchor power sums and matrix invariants* of the compiler ( $p_n = 2 + 2^n$ ,  $\det R=8$ ,  $\sum L=40$ ). The cascade is the *UV $\rightarrow$ IR ordering*; the compiler is its *IR endpoint*, where the small numbers 8, 10, 12, 16 are the flavor/family/carrier data.

## 11 Direct $\varphi_0^{\text{ret}}$ relations: old vs current

The old cascade’s “fundamental relations near  $n = 0$ ” connect directly to the current note — one is *identical*, two are early forms of current refinements:

| Quantity        | old (V1.06)                                  | current                                                                          | relation                                                                                   |
|-----------------|----------------------------------------------|----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| $\Omega_b$      | $\varphi_0^{\text{ret}}(1 - 2c_3) = 0.04894$ | $(1 - \frac{1}{4\pi})\varphi_0^{\text{ret}} = 0.04894$                           | <b>identical</b> ( $2c_3 = \frac{1}{4\pi}$ ) <span style="color: green;">[I]</span>        |
| $V_{us}/V_{ud}$ | $\sqrt{\varphi_0^{\text{ret}}} = 0.2306$     | $\lambda_C = \sqrt{\varphi_0^{\text{ret}}(1 - \varphi_0^{\text{ret}})} = 0.2244$ | refined (the $(1 - \varphi_0^{\text{ret}})$ factor) <span style="color: green;">[I]</span> |
| $r$ (tensor)    | $(\varphi_0^{\text{ret}})^2 = 0.00283$       | $12/N_\star^2 = 0.00397$                                                         | two branches, same order <span style="color: brown;">[P]</span>                            |

Marker key: [I] exact identity · [L] Lie/lattice theorem · [F] formalised · [N] numerical fixed point · [P] physical/conditional · [A] axiom / open.

So  $\Omega_b = \varphi_0^{\text{ret}}(1 - 2c_3)$  was already the exact current formula in V1.06; the Cabibbo ratio gained its  $(1 - \varphi_0^{\text{ret}})$  factor; and the old direct  $r = (\varphi_0^{\text{ret}})^2$  and the current Starobinsky  $r = 12/N_\star^2$  agree in order ( $\sim 0.003$ ) but are distinct predictions — a clean, testable discriminant, stated honestly.

## 12 Sector inventory: have all the old-cascade sectors been computed?

The old cascade also carried *calibrated absolute scales*: per block, one unit  $\zeta_B$  was fixed on a single reference and every other scale in the block followed fit-free from the ratio law  $\varphi_m/\varphi_n = (D_m/D_n)^\lambda$  (Paper V1.06, App. C). These block assignments are the place where the proton mass, the EW masses and the CMB temperature lived. The honest question is: *has the new compiler re-derived each of these, or only some?* The full inventory, with the current status spelled out:

| Old block (rung)     | Old observable & calibration                                                                                                               | Current-model status                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Mark                                   |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| near $n=0$           | $\Omega_b = \varphi_0^{\text{ret}}(1-2c_3)$ ,<br>$V_{us}/V_{ud} = \sqrt{\varphi_0^{\text{ret}}}$ ,<br>$r = (\varphi_0^{\text{ret}})^2$     | <b>covered</b> — dimensionless, derived from $\{c_3, \varphi_0^{\text{ret}}\}$ ; see the $\varphi_0^{\text{ret}}$ -table above. $\Omega_b$ is <i>identical</i> .                                                                                                                                                                                                                                                                                                                                                                                      | <span style="color: green;">[N]</span> |
| EW, $n=12$           | $v_H = \zeta_{\text{EW}} M_{\text{P1}} \varphi_{12}$ ,<br>$M_W = \frac{1}{2} g_2 v_H$ , $M_Z$                                              | <b>scale covered, absolute scheme-level</b> — the EW scale enters the current note via the action-grammar exponent and the two-loop flow; $M_W, M_Z$ are dimensionful and remain RG/scheme outputs (one $\zeta_{\text{EW}}$ ), <i>not</i> new compiler powers.                                                                                                                                                                                                                                                                                        | <span style="color: brown;">[P]</span> |
| hadronic, $n=15, 17$ | $m_p = \zeta_p M_{\text{P1}} \varphi_{15}$ ,<br>$m_b = \zeta_b M_{\text{P1}} \varphi_{15}$ ,<br>$m_u = \zeta_u M_{\text{P1}} \varphi_{17}$ | <b>ratios closed, absolute scale an anchor.</b> The quark mass <i>ratios</i> sit on the $\varphi_0^{\text{ret}}$ -word-length ladder and are closed (integer Plücker readouts, $v_{49}/v_{71}$ ); the <i>absolute</i> values need the per-sector $\Lambda/U_f^\star$ normalisation, an anchor ( <span style="color: red;">[A]</span> ). The <b>proton mass</b> is QCD-confinement, $m_p \sim \Lambda_{\text{QCD}}$ by dimensional transmutation — a <i>cross-sector</i> ratio, listed as a genuine frontier item ( $m_p/m_e$ , <code>tfpt_4</code> ). | <span style="color: red;">[A]</span>   |
| cosmo, $n=25$        | $T_{\gamma 0} = \zeta_\gamma M_{\text{P1}} \varphi_{25}$ ,<br>$T_\nu = (\frac{4}{11})^{1/3} T_{\gamma 0}$ , $\rho_\Lambda$                 | <b>partly.</b> $\rho_\Lambda/\Lambda$ is <i>typed</i> by the action grammar and the seam ( $\Lambda$ -typing, <code>tfpt_2</code> ); $T_\nu/T_{\gamma 0}$ is standard QFT (not cascade). The <b>absolute CMB temperature</b> $T_{\gamma 0}$ is a downstream readout of the reheating pipeline (Paper 6/7), conditional — not re-derived as a compiler number.                                                                                                                                                                                         | <span style="color: brown;">[P]</span> |

### Direct answer: which sectors are closed, which are not

**Closed (derived from  $\{c_3, g_{\text{car}}, \varphi_0^{\text{ret}}\}$ ):** the dimensionless near- $n=0$  anchors ( $\Omega_b$  exactly, Cabibbo, tensor branch) and all the *dimension/rung* structure of the spine. **Scale-level only (one  $\zeta_B$  each, scheme/RG):** the EW masses  $M_W, M_Z$  and the cosmological absolute scales  $T_{\gamma 0}$  — exactly as in the current SM/cosmology notes; these were *never* pure predictions, not even in V1.06 (each needed a block unit). **Genuinely open:** the **proton mass**  $m_p$  (and  $m_p/m_e$ ) is QCD-confinement across two sectors and is *not* claimed as a compiler power — it stays a frontier item (**[A]**, tfpt\_4); the quark mass *ratios* are closed (integer Plücker, v49/v71) and only the *absolute* quark scale  $m_b, m_u$  needs the per-sector  $\Lambda/U_f^*$  normalisation, an anchor (**[A]**). So: yes, the *spine* is fully audited and the *dimensionless* sectors are derived; the *dimensionful* hadronic/cosmo absolute scales are honestly still scheme-level, with the proton mass the one explicitly open cross-sector number — nothing is silently claimed.

## 13 What is new, what is old, what stays open

### New structures found via the bridge

1. The flavor selector  $\det R = h(D_5) = 8$  is the *terminal orbit* of the  $E_8$  cascade; the compiler is the cascade's IR endpoint. **[I]**
2. The atlas branching blocks (52, 56, 60) are the cascade's *UV head* ( $n = 0, 2, 4$ ); the secondary atlas and the orbit cascade are the same spine read top-down vs. as subalgebras. **[I]**
3. The anchor power sums sit on doubled-exponent rungs:  $p_5 = 34$  ( $n=13$ ),  $\sum R = 22$  ( $n=19$ ),  $\dim G_2 = 14$  ( $n=23$ ). **[I]**
4. The cascade Coxeter rung  $D = 30 = h(E_8)$  ( $n=15$ ) ties to the exponent-centering audit  $\sum |m-15| = 56$ . **[I]**

### Honest separation

The *dimension/rung coincidences* are exact arithmetic **[I]** — they show the old and new constructions live on one  $E_8$  spine. The old cascade's *scale assignments*  $\varphi_n$  (EW at  $n=12$ , hadronic at  $n=15, 17$ , cosmo at  $n=25$ ) are a *different* mechanism from the current  $\varphi_0^{\text{ret}}$ -power mass ladder: the cascade orders *orders of magnitude* (which sector sits where) via  $e^{-\gamma}$ , while the  $\varphi_0^{\text{ret}}$ -ladder gives *values within* a sector. Both are real, complementary orderings; neither is forced onto the other. The per-sector  $\zeta$ -calibrated absolute scales (proton mass, EW masses, CMB temperature) remain scheme-level — audited one by one in §12, with the proton mass the single explicitly open cross-sector number.

**Bottom line.** The old  $E_8$  cascade was an early, correct intuition: the physically relevant numbers are exactly the even-integer  $E_8$  orbit spine  $\{8, \dots, 60\}$ . The current work *explains why* — they are the  $(D_5 \times A_3) + \mu_4$  compiler atoms and their  $E_8$  branching blocks — and identifies the spine's two ends as the compiler boundary ( $D_{\text{start}} = 60$ ,  $\det R = 8$ ). Old and new are the same structure at different resolution.

## Part III

# The self-consistency loop

### The question, and the honest answer

The theory rests on two inputs,  $c_3 = \frac{1}{8\pi}$  and  $g_{\text{car}} = 5$ . The old theory had a Möbius seam and the seed was the *start* of the  $E_8$  cascade. Run it *backwards*: can the cascade/ $E_8$  *return*  $c_3$  and  $g_{\text{car}}$ , closing a self-consistent loop? **Answer:** the *discrete* content is a closed, overdetermined fixed point —  $g_{\text{car}} = 5$  and the “8” in  $c_3$  are forced by the  $E_8$  closure. The *only* irreducible primitive left is the geometric  $\pi$  (the Möbius/boundary Gauss–Bonnet). So “two axioms” collapses to “*one* continuous primitive  $\pi$  + *one* discrete self-consistency fixed point.”

## 14 The loop for $g_{\text{car}}$ — an overdetermined fixed point

Two *independent* structural conditions, both pure Lie-theory, force  $g_{\text{car}} = 5$  once  $E_8$  is the closure object and  $A_3$  is the four-puncture family geometry:

### $g_{\text{car}} = 5$ is forced twice over

(A) rank fill.

The glue  $D_{g_{\text{car}}} \oplus A_3 \hookrightarrow E_8$  must fill the rank:  $\text{rank } D_{g_{\text{car}}} + \text{rank } A_3 = \text{rank } E_8$ , i.e.  $g_{\text{car}} + 3 = 8 \Rightarrow g_{\text{car}} = 5$ .

(B) Coxeter match.

The carrier Coxeter number must equal the  $E_8$  rank,  $h(D_{g_{\text{car}}}) = 2g_{\text{car}} - 2 = 8 \Rightarrow g_{\text{car}} = 5$ .

Both give  $g_{\text{car}} = 5$ , and the loop *closes*:  $g_{\text{car}} = 5 \Rightarrow D_5 \oplus A_3 \xrightarrow{\mu_4} E_8 \Rightarrow h(E_8) = 30 = 2 \cdot 3 \cdot 5 \Rightarrow \text{largest prime} = 5 = g_{\text{car}}$ . [I]

### Reverse glue selection — $D_5$ and $A_3$ from unimodular closure

The closure even *selects the two factors*, not just the rank. The discriminant of  $A_{\mu-1}$  is  $\mathbb{Z}_\mu$  and of  $D_g$  (odd  $g$ ) is  $\mathbb{Z}_4$ ; a common cyclic glue forces  $\mu = 4$ , hence  $A_{\mu-1} = A_3$ . The even-glue norm  $q(D_g) + q(A_3) = \frac{g}{4} + \frac{3}{4} = 2$  then forces  $g = 5$ , hence  $D_5$ . A second, independent confirmation of  $\mu = 4$  is the *mirror identity*  $\dim D_{\mu+1} + \dim A_{\mu-1} = \dim V_{D_{\mu+1}} \cdot |R^+(A_{\mu-1})|$ , i.e.  $3\mu(\mu+1) = \mu(\mu+1)(\mu-1) \Rightarrow \mu-1 = 3 \Rightarrow \mu = 4$  (the  $45 + 15 = 10 \cdot 6$  identity). So

$$\text{common } \mathbb{Z}_4 \text{ glue} + \text{root norm } 2 \Rightarrow D_5 + A_3$$

—  $g_{\text{car}} = 5$  is recovered from the closure, not just posited. [I]

### Familyful $E_8$ -closure fixed-point theorem

Among rank-filling pairs  $D_g \oplus A_m$  ( $g + m = 8$ ) admitting an integer glue index  $\sqrt{\det D_g \det A_m} = \sqrt{4(m+1)}$ , exactly two close to an even unimodular lattice:  $D_8 \oplus A_0$  (no family) and  $D_5 \oplus A_3$  (familyful). The unique familyful solution is  $D_5 \oplus A_3$ , with lattice  $\cong E_8$  and  $g_{\text{car}} = 5$ .

| $D_g + A_m$                   | $g+m$ | glue $\text{idx}^2=4(m+1)$ | integer?                      | status                          |
|-------------------------------|-------|----------------------------|-------------------------------|---------------------------------|
| $D_8 + A_0$                   | 8     | 4                          | 2                             | valid, <i>no family</i>         |
| $D_7 + A_1$                   | 8     | 8                          | —                             | no integer glue                 |
| $D_6 + A_2$                   | 8     | 12                         | —                             | no integer glue                 |
| <b><math>D_5 + A_3</math></b> | 8     | 16                         | <b><math>4= \mu_4 </math></b> | <b>valid, familyful</b> , $E_8$ |
| $D_4 + A_4$                   | 8     | 20                         | —                             | no integer glue                 |

Equivalently, with  $q(A_{\mu-1}) = \frac{\mu-1}{\mu}$  and  $g = 9 - \mu$  the norm closure  $q(D_g) + q(A_{\mu-1}) = 2$  becomes  $\mu^2 - 5\mu + 4 = 0$ , whose nontrivial root is  $\mu = 4$  ( $A_3$ ,  $g = 5$ ). So  $g_{\text{car}} = 5$  is forced *three* ways: rank-fill, Coxeter-match, and integer-glue/norm closure. [L]  
[verification/v6\_bootstrap.py]

### Bootstrap classification: $D_5 \oplus A_3$ is the *unique* familyful $E_8$ glue

$E_8$  is the unique even unimodular rank-8 lattice. Its two-factor root-lattice gluings  $L_1 \oplus L_2$  (rank = 8) that admit a *cyclic* glue are exactly those whose discriminant groups are isomorphic and cyclic:

$$D_5 \oplus A_3 (\mathbb{Z}_4), \quad E_6 \oplus A_2 (\mathbb{Z}_3), \quad E_7 \oplus A_1 (\mathbb{Z}_2), \quad A_4 \oplus A_4 (\mathbb{Z}_5).$$

Imposing the two TFPT data — one factor with a 16-dimensional half-spinor ( $\dim S_{D_g}^+ = 2^{g-1} = 16 \Leftrightarrow g = 5$ ) and one factor giving exactly  $N_{\text{fam}} = 3$  families (rank  $A_m = m = 3$ ) — selects

$$D_5 \oplus A_3 \text{ (uniquely), glue group } \mathbb{Z}_4 = |\mu_4|.$$

$E_6 \oplus A_2$  gives only 2 families,  $E_7 \oplus A_1$  only 1;  $D_8$  has non-cyclic glue  $(\mathbb{Z}_2)^2$  and  $A_8$  is a single rank-8 factor. So the carrier+family decomposition is forced.  
[verification/v15\_bootstrap\_classification.py]

Figure 3: The closed loop:  $g_{\text{car}} = 5$  builds  $E_8$ , whose Coxeter number  $30 = 2 \cdot 3 \cdot 5$  returns the carrier prime 5. The value  $g_{\text{car}} = 5$  is the unique fixed point (overdetermined by rank-fill *and* Coxeter-match).

The carrier split  $3 + 2$  and the one-generation count  $\dim S^+ = 2^{g_{\text{car}}-1} = 16$  are then automatic, as is the glue norm  $q(D_5) + q(A_3) = \frac{5}{4} + \frac{3}{4} = 2$ . The family rank is rank  $A_3 = 3 = N_{\text{fam}}$  and the glue index is  $h(A_3) = 4 = |\mu_4|$  — the Coxeter numbers of the three players are  $(h(A_3), h(D_5), h(E_8)) = (4, 8, 30) = (|\mu_4|, \det R, \text{compiler})$ .

## 15 The loop for $c_3$ — the “8” is the $E_8$ rank

The boundary normalisation is  $c_3 = 1/(8\pi)$ . Its integer is exactly the carrier Coxeter number, which the loop above equals to the  $E_8$  rank:

$$c_3 = \frac{1}{h(D_5)\pi} = \frac{1}{(2g_{\text{car}} - 2)\pi} = \frac{1}{8\pi}, \quad 8 = h(D_5) = \text{rank } E_8 = \det R = \varphi(30)$$

where  $\varphi(30) = 8$  is Euler’s totient (the number of primitive residues mod 30 = the  $E_8$  exponents) — so the “8” has *five* concordant readings. The tree seed  $\varphi_{\text{tree}} = 1/(6\pi)$  has  $6 = |R^+(A_3)| = h(E_8)/g_{\text{car}}$ , the three Gauss–Bonnet boundary cycles ( $6\pi = 3 \times 2\pi$ ). So the *discrete* parts of both  $c_3$  and  $\varphi_{\text{tree}}$  are  $E_8$ /carrier invariants; only the factor  $\pi$  is genuinely continuous.

### Honest caveat on $8\pi$

$8\pi$  is *also* the standard Einstein normalisation ( $G_{\mu\nu} = 8\pi G T_{\mu\nu}$ ). The loop *identifies* this gravitational 8 with rank  $E_8 = h(D_5)$  — a non-coincidence *if*  $E_8$  is the closure, but one should be clear that  $8\pi$  has an independent GR reading. The loop promotes the two 8’s to the same number; it does not derive  $\pi$ .

## 16 The Möbius origin of the irreducible $\pi$

What the loop does *not* remove is  $\pi$ . In the old theory this is exactly the Möbius datum: the orientable double cover of the Möbius fibre is a cylinder with two boundaries plus one  $\mathbb{Z}_2$  seam  $\Gamma$ ; Gauss–Bonnet gives  $\oint k ds = 2\pi + 2\pi + 2\pi = 6\pi$  (hence  $\varphi_{\text{tree}} = 1/(6\pi)$ ), and the  $\mathbb{Z}_2$  identification is the sheet “2” of  $30 = 2 \cdot 3 \cdot 5$ . So the Möbius seam supplies precisely the two things the discrete loop cannot: the continuous  $\pi$  and the sheet parity  $\mathbb{Z}_2$ .

### Net: two axioms $\rightarrow$ one primitive + one fixed point

$$\{c_3, g_{\text{car}}\} \longrightarrow \underbrace{\pi \text{ (Möbius/Gauss–Bonnet)}}_{\text{one continuous primitive}} + \underbrace{E_8 \text{ closure}}_{\text{one discrete fixed point}}.$$

The discrete data  $\{2, 3, 4, 5, 6, 8, 30\}$  are *all* self-consistent outputs of the  $E_8$  closure ( $g_{\text{car}} = 5$ ,  $h(D_5) = 8$ ,  $h(A_3) = 4 = |\mu_4|$ ,  $h(E_8) = 30 = 2 \cdot 3 \cdot 5$ ,  $|R^+(A_3)| = 6$ ). The only irreducible input on the *dimensionless* axis is  $\pi$ . [I] (discrete loop) / [A] ( $\pi$  is primitive)

On the *dimensionful* axis there is exactly *one* more irreducible: a single mass scale. But even that is no longer a *free* constant — fixing the physical  $\Lambda$  branch pins  $\bar{M}_{\text{Pl}}$ , so  $G_N$  is a  $\Lambda$ -metrology *output* (**origin\_theory**,  $\Lambda$ -typing); the one genuinely irreducible scale is the induced-gravity (Sakharov) anchor. So the complete honest reduction is “ $\pi$  + the  $E_8$ -closure fixed point + *one* dimensionful scale”.

*One sharpening of the “8”.* Both  $\pi$ -coefficients are  $2\pi$  times a compiler integer:  $\varphi_{\text{tree}} = 1/(6\pi)$  with  $6 = 2N_{\text{fam}}$  (three Gauss–Bonnet boundary circles) and  $c_3 = 1/(8\pi)$  with  $8 = 2|\mu_4|$  (seam winding), so  $\varphi_{\text{tree}} = (|\mu_4|/N_{\text{fam}})c_3 = \frac{4}{3}c_3$ . The *same* integer 8 is the Hawking/Einstein coefficient ( $G_{\mu\nu} = 8\pi T_{\mu\nu}$ , Appendix H): the seam normaliser, the  $E_8$  rank and the universal horizon factor are one number, overdetermined ( $8 = 2|\mu_4| = \text{rank } E_8 = h(D_5) = \varphi(30) = \det R$ ). [I] [[verification/v54\\_seam\\_horizon\\_keystones.py](#)]

## A cyclic element *inside* the hull: the order-30 Coxeter rotation ([\[verification/v55\\_coxeter\\_cycle.py\]](#))

The compiler hull carries a *literal* cyclic symmetry. Built from the  $E_8$  Cartan matrix, the Coxeter element  $c = s_1 \cdots s_8$  has **order exactly**  $h(E_8) = 30 = |\mathbb{Z}_2| \cdot N_{\text{fam}} \cdot g_{\text{car}} = 2 \cdot 3 \cdot 5$  (verified by direct matrix powers), and its eigenvalues are the primitive 30th roots  $e^{2\pi i m/30}$  with  $m$  the  $E_8$  exponents  $\{1, 7, 11, 13, 17, 19, 23, 29\}$  — which are precisely the  $\varphi(30) = 8$  totatives of 30. Hence

$$\text{rank } E_8 = 8 = \varphi(30) = \#\{\text{exponents}\} = \#\{\text{live phases of the order-30 cycle}\}$$

So the 8 in  $c_3 = \frac{1}{8\pi}$  is the count of live phases of a primitive order-30 cyclic rotation of the hull, whose period  $30 = |\mathbb{Z}_2| \cdot N_{\text{fam}} \cdot g_{\text{car}}$  is the product of the three core integers. The cyclic structure is *present in the mathematics*, not interposed.

## The compiler atoms are the $E_8$ Casimir degrees ([\[verification/v66\\_e8\\_casimir\\_degrees.py\]](#))

The load-bearing integers are not an ad-hoc list: they are the fundamental *invariant degrees* of  $E_8$  (exponents +1),

$$\deg(E_8) = \{2, 8, 12, 14, 18, 20, 24, 30\},$$

with the clean (non-trivial) readings  $2=|\mathbb{Z}_2|$ ,  $8=\text{rank } E_8$ ,  $14=\dim G_2$  (the  $[K, Q]$  commutator  $G_2$ , §Paper 2),  $20=\det L$ ,  $24=|W(A_3)|=4!$ ,  $30=h(E_8)$  (and the fittable  $12=|R(A_3)|$ ,  $18=p_4(a)=2+2^4$ ). Two exact sums close it:

$$\begin{aligned} \sum \deg(E_8) &= 128 = 2^7 \quad (\text{the de Sitter prefactor } 128c_3^4; 7=\text{scalaron exp}), \\ \sum \exp(E_8) &= 120 = |R^+(E_8)|. \end{aligned}$$

Since  $E_8$  is the audit hull, its invariant degrees being the theory's integers is *structurally expected* — an organizing simplification that confirms the  $E_8$  choice rather than a coincidence.

## Two-level foundation, and the parameter audit

**Local foundation:**  $c_3, g_{\text{car}}$  are the two operational inputs (Papers 1–2). **Global bootstrap foundation:**  $g_{\text{car}}$  and the integer in  $c_3$  are  $E_8$ -closure fixed points; only  $\pi$  is primitive. The audit:

| former input                 | status now           | recovered by                                                                 |
|------------------------------|----------------------|------------------------------------------------------------------------------|
| $g_{\text{car}} = 5$         | discrete fixed point | rank-fill, Coxeter-match, integer-glue/norm, $h(E_8)$                        |
| 8 in $c_3$                   | discrete fixed point | $h(D_5)$ , rank $E_8$ , $\det R$ , $\varphi(30)$ , $2 \mu_4 $ (seam winding) |
| 6 in $\varphi_{\text{tree}}$ | discrete fixed point | $ R^+(A_3)  = h(E_8)/g_{\text{car}}$                                         |
| $\pi$                        | geometric primitive  | Möbius / Gauss–Bonnet ( <i>not</i> derived)                                  |
| $\varphi_0^{\text{ret}}$     | derived readout      | $\frac{4}{3}c_3 + 48c_3^4$                                                   |

**Correct one-liner:** *TFPT has no freely tunable fundamental numbers left; the only remaining continuous origin is  $\pi$  from the Möbius boundary geometry.* (Not “zero axioms”.)

[I]/[A]

## 17 Honest status: bootstrap, not creation from nothing

- **What is genuinely shown [I]:**  $g_{\text{car}} = 5$  is an *overdetermined* fixed point of the  $E_8$  closure (two independent Lie-theory conditions); the integer “8” in  $c_3$  is the carrier Coxeter =  $E_8$  rank; the discrete data closes a loop. The earlier landscape scan confirms  $g_{\text{car}} = 5$  is the *unique* value at which all hierarchies/family/gauge close — so the fixed point is unique, not one of many. **This uniqueness is now machine-formalised [F] in Lean 4** (Theorem A, `lean4-carrier-rigidity`): the division-free Pascal condition  $2^g = g^2 + g + 2$  has the *unique* solution  $g = 5$  (`carrier_rank_pascal_unique`; growth lemma for  $g \geq 6$ ;  $N_{\text{fam}} = (2^4 - 1)/5 = 3$ ,  $g + N_{\text{fam}} = 8$ ), audited to use only the standard kernel axioms. The 2026-06-11 hardening round adds two formal modules: `AnchorLadder.lean` (the anchor power-sum law  $p_n(a) = 2 + 2^n$  for *all*  $n$ , the ladder atoms (3, 4, 6, 10), 240/8/248, and the binary ladder  $p_{n+1} - p_n = 2^n$  as general theorems) and `PascalLadder.lean` (the odd-midpoint ladder identity  $\sum_{k \leq K} \binom{2K+1}{k} = 2^{2K}$  for *all*  $K$  via Mathlib, plus the kernel-decidable bounded uniqueness of the  $\bar{K}=2$  carrier case) — the solves-side of the Pascal Ladder Theorem ([`verification/v108_pascal_ladder.py`]) is thereby [F].
- **What this is *not*:** a derivation from zero inputs. A self-consistency loop is consistent *at* a value; uniqueness is what makes it predictive (and that is supplied by the landscape scan). The continuous  $\pi$  is not produced by the loop — it is the Möbius/boundary geometry, the one irreducible primitive.
- **Conceptual gain:** the theory’s foundation tightens from “two free axioms” to “*the*  $E_8$ -closure fixed point + the geometric  $\pi$ .” That is the Möbius self-consistency you intuited: the seed is the start of the cascade, and the cascade returns the seed’s discrete content.

## Part IV

# Open items and the $E_8$ -slice scan

## 18 The honest open-items list

This is the complete current ledger of what is *not* fully closed, graded by how hard the gap is.

Marker key: [I] exact identity · [L] Lie/lattice theorem · [F] formalised · [N] numerical fixed point · [P] physical/conditional · [A] axiom / open.

**Net.** Items 1 are finite arithmetic; 2 are standard RG; 3 hinge on named hypotheses (RP, the  $\Lambda$  branch, the UV completion); 4 are the two irreducible axioms; 5–6 are honestly open. The inflation sector (the only cosmology piece the compiler *does* sharpen) is now a parameter-free prediction ( $M=c_3^{7/2}\bar{M}_{\text{Pl}}$ , document 2).

### Item 1b closed: the explicit solar-angle Majorana texture [N]

The last open SM angle is now realised by an *explicit* texture, not a fitted number. Take the  $\mu\tau$ -symmetric Majorana matrix (tri-bimaximal at  $\varepsilon=0$ )

$$M_\nu(\varepsilon) = \begin{pmatrix} -\eta(\varepsilon) & 1 & 1 \\ 1 & 1 & 0 \\ 1 & 0 & 1 \end{pmatrix}, \quad \eta(\varepsilon) = \frac{2\sqrt{2}}{\tan 2\theta_{12}} - 1, \quad \sin^2 \theta_{12} = \frac{1}{3}(1 - 2\varepsilon). \quad (1)$$

$\mu\tau$ -symmetry forces  $\theta_{23} = 45^\circ$  and  $\theta_{13} = 0$  *exactly*; diagonalisation at the TFPT solar

deviation  $\varepsilon = \frac{3}{4}\varphi_0^{\text{ret}}$  gives

$$\sin^2 \theta_{12} = \frac{1}{3} - \frac{\varphi_0^{\text{ret}}}{2} = 0.306747, \quad \theta_{23} = 45^\circ, \quad \theta_{13} = 0 \quad [\text{N}] \quad (2)$$

**Honest residual** ([verification/v9\_neutrino\_texture.py]). The texture and the angle are exact. The seam identification is  $\varepsilon = \frac{3}{4}\varphi_0^{\text{ret}} = \frac{3}{4}(\frac{1}{6\pi} + \frac{3}{256\pi^4}) = c_3 + \frac{9}{1024\pi^4}$ : the *leading geometric term is exactly*  $c_3 = \frac{1}{8\pi}$ , and the 0.23% residual is purely the  $\varphi_0^{\text{ret}}$  seed tail (document 2). So  $\varepsilon = c_3$  holds at leading order; the full  $\varepsilon = \frac{3}{4}\varphi_0^{\text{ret}}$  is what enters the texture. The reactor angle  $\theta_{13}$  ( $\sin^2 \theta_{13} = e^{-5/6}\varphi_0^{\text{ret}}$ , document 2) enters through a separate  $\mu\tau$ -breaking term and is not part of this minimal solar texture. **Scope:** this realises the TFPT solar shift in the  $\mu\tau$ -symmetric *limit*; it is *not* the full PMNS matrix. The  $\theta_{23}=45^\circ$  value is the symmetric-limit centre, *not* an octant prediction — current global fits (NuFIT 6.0) leave the octant unresolved — and the reactor angle plus the combined matrix require the separately stated  $\mu\tau$ -breaking channel.

## 19 The $E_8$ -slice scan: results (honest hit / miss)

All seven maximal slices of 248 were scanned for the unassigned quantities. The rule was a meaningful (low-complexity) compiler/slice expression matching to  $< 0.5\%$ ; matches that need a free fitted factor are reported as *misses*.

| Slice / target                       | Result                                                                                                                                                                                             | Verdict        |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| $A_4 \times A_4 = SU(5)^2$           | $\sin^2 \theta_W _{\text{GUT}} = 3/8$ sits in the $SU(5)$ hypercharge embedding; the 12 coset states are the proton-decay $X, Y$ bosons                                                            | [I] (known)    |
| $F_4 \times G_2$ / Koide             | Koide $Q = 2/3 =  \mathbb{Z}_2 /N_{\text{fam}}$ (sheet over families); $J_3(\mathbb{O})$ has $\dim 27=26+1$ , $3 \times 3$ octonionic “generations” on the diagonal                                | [P] structural |
| $D_8 = SO(16)$                       | $128 = (16, 4) \oplus (\overline{16}, \overline{4})$ — <i>same</i> spinor as $D_5 \times A_3$ ; $\nu_R$ (seesaw) lives in the 16; <b>no new dark-matter state</b> (only the 4th $\mu_4$ direction) | [I]            |
| $A_8 = SU(9)$ , $9=3 \times 3$       | $\Lambda^3(3, 3) = (10, 1) \oplus (8, 8) \oplus (1, 10)$ : the $(8, 8)=64$ dominates — naive family $\times$ colour <b>fails</b>                                                                   | miss           |
| $A_8 \supset SU(5) \times SU(4)$     | $\Lambda^3(5+4)$ contains the SM <b>10</b> : a genuine chiral-family-unification <i>lead</i> , but not TFPT-forced                                                                                 | lead           |
| $E_6 \times A_2$ / Jarlskog          | cross term $2(\mathbf{1}^\top Ra)N_{\text{fam}} = 162 = 248 - 78 - 8$ exact; $J \sim \lambda_Y^6$ only to right order, no clean hit                                                                | weak           |
| $E_8$ theta shells                   | root shells 240, 2160, 6720, $\dots$ ; $31=2^{g_{\text{car}}}-1$ is <i>not</i> a clean shell ratio                                                                                                 | inconcl.       |
| $m_p/m_e = 1836.15$                  | no clean $E_8$ /compiler expression (a QCD-confinement ratio); apparent hits need a free factor                                                                                                    | <b>miss</b>    |
| $\eta_B \approx 6.1 \times 10^{-10}$ | sits <i>between</i> $c_3^6=4 \times 10^{-9}$ and $c_3^7=1.6 \times 10^{-10}$ ; right order, no integer power                                                                                       | order only     |

### Genuine new readings the scan produced

- **Koide** =  $|\mathbb{Z}_2|/N_{\text{fam}}$ . The empirical Koide value  $2/3$  is exactly the sheet over the family count — a clean (if simple) compiler reading, promoting Koide from “near  $2/3$ ” to “democratic  $|\mathbb{Z}_2|/N_{\text{fam}}$ .”
- **$E_8$  as the optimal 8-bit code.**  $E_8$  is the optimal 8D lattice (kissing number 240). In byte framing  $256-248 = 8 = \text{rank } E_8$  and  $256-240 = 16 = \dim S^+$  — a clean information-theoretic reading of the two load-bearing  $E_8$  numbers.
- **Dark matter = no new state.** The  $SO(16)$  scan shows the 128 is the *same* matter

spinor; there is no spare  $E_8$  singlet to be a WIMP. Any DM candidate must be the determinant-line axion (frontier doc), not a new  $E_8$  rep — a useful *negative*.

- $SU(9) \supset SU(5) \times SU(4)$  **chiral lead**.  $\Lambda^3$  puts the SM **10** in the antisymmetric; the cleanest unexploited route to a family-unification reading, flagged for future work.

### Honest negatives

$m_p/m_e$  has *no* clean  $E_8$ /compiler derivation (it is a confinement ratio — the apparent “hits” all need a free fitted factor);  $\eta_B$  matches only at the order-of-magnitude level ( $\sim c_3^{6.x}$ ); the  $\Lambda$  rec/car branch is *not* selected by the theta series; the Jarlskog invariant is right only to order  $\lambda_Y^6$ . These are reported as open, not forced.

## 20 Following the $SU(9)$ lead: cross-slice consistency

The one scan lead worth following is  $A_8 = SU(9) \supset SU(5) \times SU(4)$ . Splitting  $9 = (5, 1) \oplus (1, 4)$  the  $E_8$  branching  $248 = 80 \oplus 84 \oplus \overline{84}$  decomposes *exactly* as:

| piece              | $SU(5) \times SU(4)$ content                                                  | reading                                               |
|--------------------|-------------------------------------------------------------------------------|-------------------------------------------------------|
| 80 (adj)           | $(24, 1) + (1, 15) + (5, \bar{4}) + (\bar{5}, 4) + (1, 1)$                    | $SU(5)_{\text{GUT}} + SU(4)_{\text{fam}}$ gauge       |
| $84 = \Lambda^3 9$ | $(10, 1) + (10, 4) + (5, 6) + (1, 4)$                                         | the SM <b>10</b> as family-singlet + family- <b>4</b> |
| $\overline{84}$    | $(\overline{10}, 1) + (\overline{10}, \bar{4}) + (\bar{5}, 6) + (1, \bar{4})$ | the conjugate matter                                  |

(Dimension checks:  $24+15+20+20+1 = 80$ ;  $10+40+30+4 = 84$ ; total 248.)

### The genuine content: $A_8$ and $D_5 \times A_3$ agree on the family [I]

The  $SU(4)$  here is *the same*  $A_3$  family group as in the construction slice  $D_5 \times A_3$  — the four punctures  $\mu_4$  of  $\mathbb{P}^1 \setminus \mu_4$ . The  $SU(5)$  is the Georgi–Glashow GUT sitting inside the carrier  $SO(10) = D_5$  ( $SU(5) \subset SO(10)$ ). So the two maximal slices are *consistent*: both read the family as  $SU(4)=A_3$ , and  $A_8$  additionally exposes the  $SU(5)$  matter content — the SM **10** appears as  $(10, 1) \oplus (10, 4)$ , i.e. a family-singlet **10** plus a family-**4**, where the **4** of  $A_3$  is exactly TFPT’s “ $4 = N_{\text{fam}} + 1$ ” (three families + the  $\mu_4$  direction).

### Honest limit: chirality is still the index, not $E_8$

$84 \oplus \overline{84}$  is *vectorlike* ( $10 \oplus \overline{10}$  etc.):  $E_8$  being non-chiral, the slice cannot by itself produce three *chiral* generations. The chirality is the boundary index  $\text{Ind}(D_{\text{fam}}^+) = 3$  — the *same* input TFPT already uses. So  $SU(9)$  is a consistent re-reading (matter in  $SU(5)$ , family in  $A_3$ ), not an independent derivation of  $N_{\text{fam}} = 3$ . Each  $SU(5)$  pair (**10** + **5**) is anomaly-free, so the embedding is clean. [P]

## Appendix: computational verification

The audit/bridge identities of this document (marked [I], [L]) are re-derived from  $\{c_3, g_{\text{car}}\}$  and machine-checked by the suite in the repository folder `verification/`; the inline tags `[verification/...]` point to the exact script. Relevant here:

- `v1_e8_glue.py` — the  $\mu_4$  glue  $E_8 = (D_5 \oplus A_3) + \mu_4$  (load-bearing).
- `v4_flavor_matrix.py` — the spectral selector  $\det R = h(D_5) = 8$ , minors  $\{2, 3, 5\}$ .

- `v5_e8_cascade.py` — the cascade  $D_n=60-2n$ : endpoints, exponent rungs, IR tail, variance.
- `v6_bootstrap.py` — the self-consistency loop:  $\mu^2-5\mu+4=0$ ,  $g_{\text{car}}=5$  three ways, 8=rank  $E_8$ .

The  $E_8$ -slice/atlas readings are explicitly **[A]** (audit-level), not part of the pass/fail suite. Run `python verification/run_all.py`; full map in `verification/README.md`.
